Patients must stay on these medications in order to experience relief, because there is no known cure for this disorder. PLMD can cause insomnia and daytime sleepiness. How is PLMD diagnosed? PLMS can range from a small amount of movement in the ankles and toes, to wild flailing of all four limbs. For women, the presence of musculoskeletal disease, heart disease, obstructive sleep apnea, cataplexy, doing physical activities close to bedtime and the presence of a mental disorder were significantly associated with having a higher risk of both PLMD and restless legs syndrome. PLMD is diagnosed with a medical history, often including a sleep history from a bed partner, and a physical exam. Patients with PLMD will complain of excessive daytime sleepiness EDS, falling asleep during the day, trouble falling asleep at night, and difficulty staying asleep throughout the night. It is also advised not to consume caffeine, alcohol, or antidepressants as these substances could worsen the PLMD symptoms. Factors that increase the likelihood of PLMD in the absence of restless leg syndrome include being a shift worker, snoring, coffee drinking, stress, and use of hypnotics, particularly in the case of benzodiazepine withdrawal.
