In this trial 2, patients were randomly assigned either a placebo, a pill combining phentermine 7. Not all participants taking these treatments lost weight. Phentermine has similar pharmacological properties to amphetamines and acts by reducing appetite, while topiramate was originally marketed as an anti-epilepsy drug. The higher dose of treatment investigated here increased depression and anxiety. They note that dropout is usually a problem in these trials, although theirs was worse than seen in recent studies of two other weight loss drugs for obesity. This large randomised controlled trial describes a study assessing the effects of a new treatment for weight loss in overweight and obese individuals. Certain side effects may lead to discontinuation of the drug, including neuropsychiatric problems. Each also had two or more pre-specified comorbidities. It is well described and the authors raise the major limitation of their study: The researchers note that the psychiatric adverse events were mainly during the early phase of treatment and they disappeared when the drug was discontinued. The researchers have not given much focus to this limitation and say that they addressed it by analysing their available data in three different ways, which did not produce greatly differing results.
