This document is regularly reviewed and updated. The currently available data suggest that preterm delivery may be associated with gestational exposure to systemic corticosteroids. To report an exposure please download and complete a pregnancy reporting form. It should also be borne in mind that many of the studies reporting pregnancy outcomes following gestational exposure to systemic corticosteroids are limited by a lack of stratification to account for differing doses, treatment duration, and steroid potencies. Studies assessing birth weight outcomes following gestational exposure to systemic corticosteroids low birth weight, intrauterine growth restriction, small for gestational age do not provide robust evidence of an association, but are limited. Exposure to corticosteroids at any stage in pregnancy would not usually be regarded as medical grounds for termination of pregnancy or any additional fetal monitoring. Corticosteroids are a class of hormones produced in the adrenal cortex which are involved in a range of physiological functions. However, they do not rule out that this may be due to confounding as a consequence of the underlying maternal illness, rather than to steroid exposure itself, and further well-controlled studies are required to address this question. The final decision regarding which treatment is used for an individual patient remains the clinical responsibility of the prescriber. The available data do not support an association between in utero exposure to systemic corticosteroids and cardiac defects in the offspring. Clinicians are reminded of the importance of consideration of such factors when performing case-specific risk assessments.

I delivered two weeks early and my son was 7 pounds 13 ounces and healthy! I am still on 5 mg prednisone and was for most of the second and third trimesters. It's been two weeks since delivery and I am starting to have a flare.
